

# Non-Linear Budget Constraints

In-kind subsidies, partial subsidies and exclusive schemes. Each one bends the budget line somewhere different, and the optimum can land right on the fold.

## BEFORE YOU START

### Opening it

There is nothing to install. It is a web page: it opens in Chrome, Safari, Edge or Firefox, on a computer, tablet or phone. You need a connection the first time; after that the browser keeps it and it works offline.

Top right there are two pairs of buttons. The first switches the language between **ES** and **EN**; the second goes from **Dark** to **Light**. For projecting in class, light mode reads better on a beamer; on screen, dark is easier on the eyes.

**Every graph zooms.** Mouse wheel over the graph, or a two-finger pinch on the trackpad or touchscreen. The zoom applies to the graph under the pointer only, not to the whole page.

Each slider has a number box beside it. For an exact value, type it into the box and press **Enter**; the slider is for exploring, the box is for precision.

## WHAT IS ON SCREEN

### Up to three panels

| PANEL                               | WHAT IT SHOWS                                                                                                                                                     |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Plane (x, y)</b>                 | The budget frontier with its folds, the feasible set, the indifference curve through the optimum and — if you ask — a second scheme overlaid for comparison.      |
| <b>Utility along the constraint</b> | Utility traced along the frontier, from $x = 0$ to the far end. The optimum is this curve's maximum, and here you can see why it sometimes lands on a sharp peak. |
| <b>3D surface</b> · $z = u(x, y)$   | Optional, at the foot of the screen. The same constraint lifted onto the utility surface: the optimum is the summit of the arch.                                  |

## The readouts

| READOUT                 | HOW TO READ IT                                                                                                          |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------|
| $x^*, y^*, u(x^*, y^*)$ | The optimal bundle and its utility.                                                                                     |
| Cost                    | What the programme costs whoever funds it.                                                                              |
| Cash advantage          | How much more utility a cash transfer of the same cost would reach. This is the number that carries the argument.       |
| Kind of optimum         | Tangency, kink, corner or jump edge. Each needs a different argument, and only the first admits “MRS = relative price”. |
| Slope at $x_s$          | How much the frontier's slope changes as you cross the allowance.                                                       |
| Jump at $x_s$           | How far the frontier drops vertically at the allowance. Zero except in the exclusive schemes.                           |

## THE SEVEN SCHEMES

### What each one does

All of them start from the same income  $m$  and the same prices. What changes is where and how the line bends. The allowance is called  $x_s$  and the subsidy intensity  $s$ .

| SCHEME                                    | THE FRONTIER IT PRODUCES                                                                                                                                                                                                                            |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Simple constraint</b>                  | The ordinary line, no programme. The benchmark.                                                                                                                                                                                                     |
| <b>In-kind subsidy (non-exclusive)</b>    | The first $x_s$ units of $x$ are free. The frontier starts <b>flat</b> up to $x_s$ and from there falls with the normal slope. Cost: $p_x \cdot x_s$ .                                                                                              |
| <b>Partial in-kind subsidy</b>            | A discount of $s$ on the first $x_s$ units. The frontier starts with slope $(1-s) \cdot p_x/p_y$ and then reverts to normal. Cost: $s \cdot p_x \cdot x_s$ .                                                                                        |
| <b>Exclusive subsidy (public schools)</b> | Like the in-kind one, but <b>going past the allowance forfeits the whole grant</b> . The frontier drops vertically at $x_s$ and continues from the original line. The standard example is public schooling: enrol elsewhere and you lose the place. |
| <b>Partial exclusive subsidy</b>          | The same with a discount instead of free units. The drop is smaller but it is there.                                                                                                                                                                |
| <b>Cash equivalent (full)</b>             | A cash transfer of $p_x \cdot x_s$ . The line shifts outward, parallel, with no bend.                                                                                                                                                               |
| <b>Cash equivalent (partial)</b>          | The same with $s \cdot p_x \cdot x_s$ . The fair rival to the partial subsidy.                                                                                                                                                                      |

The **s** slider reaches down to  $-1$ . With  $s$  negative the programme stops being a subsidy and becomes a **tax** at rate  $\tau = |s|$  on the first  $x_s$  units: the frontier bends inward instead of outward.

## Compare with

The **Compare with** menu overlays a second scheme in another colour. The comparison that matters is nearly always against the cash transfer of equal cost, and that is the default.

### THE CLASSIC ARGUMENT, IN NUMBERS

## Cash versus in-kind

The standard result is that a cash transfer is never worse for the recipient than an in-kind subsidy of the same cost, and is sometimes strictly better. You can check that in two minutes [here](#) and — more importantly — see *when* there is a difference and when there is not.

- 1 Set **Cobb-Douglas**,  $p_x = 2$ ,  $p_y = 2$ ,  $m = 20$ ,  $x_s = 4$ . Pick the scheme **In-kind subsidy (non-exclusive)** and compare with the **Cash equivalent (full)**.

Programme cost:  $p_x \cdot x_s = 8$ .

- 2 Leave  $a = 0.5$ . Look at the two optima.

Both give  $x^* = 7$ ,  $y^* = 7$ ,  $u = 7$ . **A tie**. The optimum lands where the two frontiers coincide, so the allowance does not bind.

- 3 Now lower  $a$  to **0.15**. The consumer stops wanting so much  $x$ .

In kind:  $x^* = 4$ ,  $y^* = 10$ ,  $u = 8.716$ , and the applet classes it as a **kink**. In cash:  $x^* = 2.1$ ,  $y^* = 11.9$ ,  $u = 9.174$ . **Cash wins**.

- 4 That is the whole moral: an in-kind subsidy only hurts when it *pushes*. At  $a = 0.5$  the consumer already wanted 7 units and the 4 free ones force nothing; at  $a = 0.15$  he only wanted 2.1, and the programme parks him at 4.

## What exclusion adds

Exclusive schemes are worse still, and for a different reason. At the same cost they do not merely bend the frontier: they **break** it.

- 1 Go back to  $a = 0.5$  and change the scheme to **Exclusive subsidy**, with the same  $p_x = 2$ ,  $p_y = 2$ ,  $m = 20$ ,  $x_s = 4$ .

$x^* = 4$ ,  $y^* = 10$ ,  $u = 6.325$ . The optimum type is **jump edge**.

- 2 Compare it with the non-exclusive in-kind subsidy, which cost the same (8) and gave  $u = 7$ .

The same public money, 0.675 less utility. The only thing that changed is the exclusion rule.

- 3 Switch on the **Kinks** layer and look at the **Utility along the constraint** panel: the curve drops at  $x_s$ . The consumer sticks to the left edge of the drop because crossing it costs the whole grant.

This is the applet's policy reading: it is not only how much is spent, but what shape of frontier the recipient is left with. A badly designed programme can spend the same and be worth less.

## What it is for

The **3D surface** switch opens a panel at the foot with the same utility function drawn in height, and the budget frontier lifted onto it. The optimum, a tangency point in the plane, is here simply the summit of the arch: for many people that is the picture that makes it click.

| CONTROL                               | WHAT IT DOES                                                                                                                               |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>3D</b>                             | Free perspective view. Drag to rotate the camera, wheel to zoom.                                                                           |
| <b>X-Z</b>                            | Orthogonal projection onto the plane $y = 0$ . Utility against $x$ alone.                                                                  |
| <b>X-Y</b>                            | Projection onto $z = 0$ : the view from above. Literally the contour map, and useful for showing where contours come from.                 |
| <b>Y-Z</b>                            | Projection onto $x = 0$ : utility against $y$ .                                                                                            |
| <b>Shade outside the feasible set</b> | Washes out the colour of the part of the surface you cannot afford. Only the affordable slice stays lit, which is where the problem lives. |
| <b>XY plane</b>                       | Draws the floor $z = 0$ and projects the frontier onto it, so you see the lifted curve and its shadow at once.                             |

The three projections are **orthographic**, not perspective: nothing foreshortens, so distances compare directly. The free view is perspective, which reads better as a solid but misleads about measurements.

## AXES AND LAYERS

### Setting the axes

By default the axes are **fixed** at the ceilings you type, so two schemes compare at the same scale. If the frontier leaves the frame a warning appears: raise the ceiling or tick **Fit the axes automatically**.

## The layers

| LAYER                     | WHAT IT DRAWS                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------|
| Heat gradient             | The coloured utility map. Turn it off and the background goes plain; the indifference curves keep their height colour. |
| Contours                  | Indifference curves at regular levels.                                                                                 |
| Feasible set              | Darkens everything outside the budget.                                                                                 |
| Curve through the optimum | The indifference curve through the solution.                                                                           |
| Optimum                   | The point. Turn it off while the student looks for it.                                                                 |
| Vertices                  | Marks the folds and the jumps of the frontier.                                                                         |
| Compared set              | The feasible area of the second scheme.                                                                                |
| Grid                      | The grid.                                                                                                              |

## WRITING YOUR OWN FUNCTION

## The syntax it accepts

In the custom preferences box the variables are **x** and **y**. The optimum is found by walking the frontier piece by piece and also testing both ends of every piece, so kinks and jumps are found properly even where the first-order condition says nothing.

| CONTROL                            | WHAT IT DOES                                                                        |
|------------------------------------|-------------------------------------------------------------------------------------|
| <code>+ - * / ^</code>             | Add, subtract, multiply, divide, power. <code>x^0.5</code> is the square root of x. |
| <code>( )</code>                   | Brackets. <code>(x+y)^2</code> is not the same as <code>x+y^2</code> .              |
| <code>sqrt ln log exp abs</code>   | Root, natural log, base-10 log, exponential and absolute value.                     |
| <code>min max</code>               | Two arguments: <code>min(x,y)</code> is perfect complements.                        |
| <code>sin cos</code>               | Trigonometric, in radians. Rarely useful here, but available.                       |
| <code>e pi</code>                  | The two constants. <code>e</code> is 2.718..., <code>pi</code> is 3.1416...         |
| <code>2x</code> , <code>3xy</code> | Implicit multiplication works: <code>2x</code> reads as <code>2*x</code> .          |

## Examples that work

| EXPRESSION       | WHAT PREFERENCES IT DESCRIBES                                                      |
|------------------|------------------------------------------------------------------------------------|
| $x^{0.3}y^{0.7}$ | Cobb–Douglas weighted towards y: the x allowance tends to bind.                    |
| $\min(x, y)$     | Perfect complements. The optimum jumps from fold to fold.                          |
| $x+2y$           | Perfect substitutes: corner solutions, and the subsidy can flip them.              |
| $\ln(x)+y$       | Quasilinear: demand for x does not depend on income, so the allowance shows clean. |

If it cannot be read you get “*I can't read that expression*” and the graph stays as it was. The usual causes are an unclosed bracket, a decimal comma instead of a point ( 0,5 instead of 0.5 ) or a variable other than x and y.

## IF SOMETHING GOES WRONG

## Common problems

| SYMPTOM                                       | WHAT TO DO                                                                                                                                          |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| It says “The frontier runs outside the frame” | Raise the x or y ceiling, or tick <b>Fit the axes automatically</b> . With a large $x_s$ the frontier stretches a long way.                         |
| The two schemes look identical                | That is a result, not a bug: the allowance is not biting. Lower the preference parameter a, or raise $x_s$ , until the optimum lands on the fold.   |
| The cash advantage comes out zero             | Same thing: the optimum is on the stretch where the two frontiers coincide. That is exactly the case where giving in kind costs nothing in welfare. |
| The 3D panel is slow                          | Close the substitution panel, or lower the axis ceilings. The mesh is rebuilt as you rotate.                                                        |
| I cannot get back to the free view            | Press the <b>3D</b> button in the view group, or just drag on the panel: dragging leaves the projection.                                            |

Open the applet: **Non-Linear Budget Constraints**. It all runs in the browser, and once loaded, offline too.

[← Back to the menu](#)
